**TABLE 6.4** Heats of Fusion, Vaporization, and Sublimation and Specific Heat at Various Temperatures of the Elements and Inorganic Compounds

*Abbreviations Used in the Table*

$\Delta Hm$ , enthalpy of melting (at the melting point) in  $\text{kJ} \cdot \text{mol}^{-1}$   
 $\Delta Hv$ , enthalpy of vaporization (at the boiling point) in  $\text{kJ} \cdot \text{mol}^{-1}$   
 $\Delta Hs$ , enthalpy of sublimation (or vaporization at 298 K) in  $\text{kJ} \cdot \text{mol}^{-1}$   
 $C_p$ , specific heat (at temperature specified on the Kelvin scale) for the physical state in existence (or specified: c, lq, g) at that temperature in  $\text{J} \cdot \text{K}^{-1} \cdot \text{mol}^{-1}$   
 $\Delta Ht$ , enthalpy of transition (at temperature specified, superscript, measured in degrees Celsius) in  $\text{kJ} \cdot \text{mol}^{-1}$

| Substance                                                | $\Delta Hm$ | $\Delta Hv$ | $\Delta Hs$          | $C_p$     |           |         |          |

6.2 CRITICAL PHENOMENA

The *critical temperature*,  $T_c$ , of a gas is the temperature above which the gas cannot be liquefied no matter how high the pressure.

The *critical pressure*,  $P_c$ , is the lowest pressure which will liquefy the gas at its critical temperature.

The *critical volume*,  $V_c$ , is the volume of 1 mol at the critical temperature and the critical pressure. It can be computed from the critical density,  $\rho_c$ , as follows:

$$\frac{\text{Molecular weight (in g} \cdot \text{mol}^{-1})}{\rho_c \text{ (in g} \cdot \text{cm}^{-3})} = V_c \text{ (in cm}^3 \cdot \text{mol}^{-1})$$

The critical pressure, critical molar volume, and critical temperature are the values of the pressure, molar volume, and thermodynamic temperature at which the densities of coexisting liquid and gaseous phases just become identical. At this critical point, the *critical compressibility factor*,  $Z_c$ , is:

$$Z_c = \frac{P_c V_c}{RT_c}$$

**TABLE 6.5** Critical Properties

## 7.1 X-RAY METHODS

An X-ray tube operating at a voltage  $V$  (in keV) emits a continuous X-ray spectrum, the minimum wavelength of which is given by  $\lambda_{\min} = 12.398/V$  with the wavelength expressed in angstroms. For expressing the wavelength in  $kX$  units, divide by the factor 1.00202. Tables 7.1 and 7.2 are based

**TABLE 7.1** Wavelengths of X-Ray Emission Spectra in Angstroms

| Atomic No. | Element | $K\alpha_2$ | $K\alpha_1$ | $K\beta_1$ | $L\alpha_1$ | $L\beta_1$ |
|------------|---------|-------------|-------------|------------|-------------|------------|
| 3          | Li      | 240         |             |            |             |            |

on the  $K$  and  $L$  wavelength values as published by Y. Cauchois and H. Hulubei (*Tables de Constantes et Données Numériques, I. Longueurs d'Onde des Émissions X et des Discontinuités d'Absorption X*, Hermann, Paris, 1947) and by the International Union of Crystallography (*International Tables for X-Ray Crystallography*, Kynoch Press, Birmingham, England, 1962). Wavelength accuracy is only to about 1 in 25 000 except for the lines employed in X-ray diffraction work.

Use of energy-proportional detectors for X-rays creates a need for energy values of  $K$  and  $L$  absorption edges (Table 7.3) and emission series (Table 7.4). These values were obtained by a conversion to keV of tabulated experimental wavelength values and smoothed by a fit to Moseley's law. Although values are listed to 1 eV, chemical form may shift absorption edges and emission lines as much as 10 to 20 eV. S. Fine and C. F. Hendee [*Nuclonics*, **13**(3):36 (1955)] also give values for  $K\beta_2$ ,  $L\gamma_1$ , and  $L\beta_2$  lines.

The relative intensities of X-ray emission lines from targets varies for different elements. However, one can assume a ratio of  $K\alpha_1/K\alpha_2 = 2$  for the commonly used targets. The ratio of  $K\alpha_2/K\beta_1$  from these targets varies from 6 to 3.5. The intensities of  $K\beta_2$  radiations amount to about 1 percent

of that of the corresponding  $K\alpha_1$  radiation. In practical applications these ratios have to be corrected for differential absorption in the window of the tube and air path, the ratio of scattering factors for and differential absorption in the crystal, and for sensitivity characteristics of the detector. Generalizing, the intensities of radiations from the  $K$  and  $L$  series are as follows:

| Emission line      | $K\alpha_1$ | $K\alpha_2$ | $K\beta_1$ | $K\beta_2$ | $L\alpha_1$ | $L\alpha_2$ | $L\beta_1$ | $L\beta_2$ | $L\gamma_1$ |
|--------------------|-------------|-------------|------------|------------|-------------|-------------|------------|------------|-------------|
| Relative intensity | 500         | 250         | 80–150     | 5          | 100         | 10          | 30         | 60         | 40          |

For angles at which the  $K\alpha_1$ ,  $K\alpha_2$  doublet is not resolved, a mean wavelength [ $K\bar{\alpha} = (2K\alpha_1 + K\alpha_2)/3$ ] can be used.

**Filters.** The  $K$  spectra of the light metals, often used as target material in the production of X-rays for diffraction studies, contain three strong lines,  $\alpha_1$ ,  $\alpha_2$  and  $\beta_1$ , of which the  $\alpha$  lines form a doublet with a narrow wavelength separation. The  $K\beta$  radiation can be eliminated by using a thin foil filter, usually of the element of next lower atomic number to that of the target element: the  $K\alpha$  lines are transmitted with a relatively small loss of intensity. Table 7.5, restricted to the  $K$  wavelengths of target elements in common use, lists the calculated thicknesses of  $\beta$  filters required to reduce the  $K\beta_1/K\alpha_1$  integrated intensity ratio to  $1/100$ .

**Interplanar Spacings.** Diffractometer alignment procedures require the use of a well-prepared polycrystalline specimen. Two standard samples found to be suitable are silicon and  $\alpha$ -quartz (including Novaculite). The  $2\theta$  values of several of the most intense reflections for these materials are listed in Table 7.6 (*Tables of Interplanar Spacings  $d$  vs. Diffraction Angle  $2\theta$  for Selected Targets*, Picker Nuclear, White Plains, N.Y., 1966). To convert to  $d$  for  $K\bar{\alpha}$  or to  $d$  for  $K\alpha_2$ , multiply the tabulated  $d$  value (Table 7.6) for  $K\alpha_1$  by the factor given below:

| Element | $K\bar{\alpha}$ | $K\alpha_2$ |
|---------|-----------------|-------------|
| W       | 1.007 69        | 1.023 07    |
| Ag      | 1.002 63        | 1.007 89    |

| Cu      | 1.000 82        | 1.002 48    |
| Ni      | 1.000 77        | 1.002 32    |
| Co      | 1.000 72        | 1.002 16    |
| Fe      | 1.000 67        | 1.002 04    |
| Cr      | 1.000 57        | 1.001 70    |

**Analyzing Crystals.** The range of wavelengths usable with various analyzing crystals are governed by the  $d$  spacings of the crystal planes and by the geometric limits to which the goniometer can be rotated. The  $d$  value should be small enough to make the angle  $2\theta$  greater than approximately 10 or 15 deg, even at the shortest wavelength used: otherwise excessively long analyzing crystals would be needed to prevent the direct fluorescent beam from entering the detector. A small  $d$  value is also favorable for producing a large dispersion of the spectrum to give good separation of adjacent lines. On the other hand, a small  $d$  value imposes an upper limit to the range of wavelengths that can be analyzed. Actually the goniometer is limited mechanically to about 150 deg for a  $2\theta$  value. A final requirement is the reflection efficiency and minimization of higher-order reflections. Table 7.7 gives a list of crystals commonly used for X-ray spectroscopy.

| Potassium hydrogen phthalate (KAP)  | 10 $\bar{1}$ 1   | 26.4            | Medium       |
| Lead palmitate                      |                  | 45.6            |              |
| Strontium behenate                  |                  | 61.3            |              |
| Lead stearate                       |                  | 100.4           | Medium       |

The long-wavelength analyzers are prepared by dipping an optical flat into the film of the metal fatty acid about 50 times to produce a layer 180 molecules in thickness.

Lithium fluoride is the optimum crystal for all wavelengths less than 3 Å. Pentaerythritol (PET) and potassium hydrogen phthalate (KAP) are usually the crystals of choice for wavelengths from 3 to 20 Å. Two crystals suppress even-ordered reflections: silicon (111) and calcium fluoride (111).

**Mass Absorption Coefficients.** Radiation traversing a layer of substance is diminished in intensity by a constant fraction per centimeter thickness  $x$  of material. The emergent radiant power  $P$ , in terms of incident radiant power  $P_0$ , is given by

$$P = P_0 \exp(-\mu x)$$

which defines the total linear absorption coefficient  $\mu$ . Since the reduction of intensity is determined by the quantity of matter traversed by the primary beam, the absorber thickness is best expressed on a mass basis, in g/cm<sup>2</sup>. The mass absorption coefficient  $\mu/\rho$ , expressed in units cm<sup>2</sup>/g, where  $\rho$  is the density of the material, is approximately independent of the physical state of the material and, to a good approximation, is additive with respect to the elements composing a substance.

Table 7.8 contains values of  $\mu/\rho$  for the common target elements employed in X-ray work. A more extensive set of mass absorption coefficients for  $K$ ,  $L$ , and  $M$  emission lines within the wavelength range from 0.7 to 12 Å is contained in Heinrich's paper in T. D. McKinley, K. F. J. Heinrich, and D. B. Wittry (eds.), *The Electron Microprobe*, Wiley, New York, 1966, pp. 351–377. This article should be consulted to ascertain the probable accuracy of the values and for a compilation of coefficients and exponents employed in the computations.

TABLE 7.8 Mass Absorption Coefficients for  $K\alpha_1$  Lines and  $W L\alpha_1$  Line

| Emitter<br>wavelength, Å | Ag $K\alpha_1$<br>0.559 | Mo $K\alpha_1$<br>0.709 | Cu $K\alpha_1$<br>1.541 | Ni $K\alpha_1$<br>1.658 | Co $K\alpha_1$<br>1.789 | Fe $K\alpha_1$<br>1.936 | Cr $K\alpha_1$<br>2.290 | W $L\alpha_1$<br>1.476 |

## 7.2 ULTRAVIOLET-VISIBLE SPECTROSCOPY

Molecules with two or more isolated chromophores (absorbing groups) absorb light of nearly the same wavelength as does a molecule containing only a single chromophore of a particular type. The intensity of the absorption is proportional to the number of that type of chromophore present in the molecule. Representative chromophores are given in Table 7.9.

The solvent chosen must dissolve the sample, yet be relatively transparent in the spectral region of interest. In order to avoid poor resolution and difficulties in spectrum interpretation, a solvent should not be employed for measurements that are near the wavelength of or are shorter than the wavelength of its ultraviolet cutoff, that is, the wavelength at which absorbance for the solvent alone approaches one absorbance unit. Ultraviolet cutoffs for solvents commonly used are given in Table 7.10.

Appreciable interaction between chromophores does not occur unless they are linked directly to each other, or forced into close proximity as a result of molecular stereochemical configuration. Interposition of a single methylene group, or *meta* orientation about an aromatic ring, is sufficient to insulate chromophores almost completely from each other. Certain combinations of functional groups afford chromophoric systems which give rise to characteristic absorption bands.

Sets of empirical rules, often referred to as Woodward's rules or the Woodward-Fieser rules, enable the absorption maxima of dienes (Table 7.11) and enones and dienones (Table 7.12) to be predicted. To the respective base values (absorption wavelength of parent compound) are added the increments for the structural features or substituent groups present. When necessary, a solvent correction is also applied (Table 7.13).

**TABLE 7.9** Electronic Absorption Bands for Representative Chromophores

| Chromophore  | System                                     | $\lambda_{\max}$ | $\epsilon_{\max}$ |
|--------------|--------------------------------------------|------------------|-------------------|

**TABLE 7.11** Absorption Wavelength of Dienes

Heteroannular and acyclic dienes usually display molar absorptivities in the 8000 to 20 000 range, whereas homoannular dienes are in the 5000 to 8000 range.

Poor correlations are obtained for cross-conjugated polyene systems such as

The correlations presented here are sometimes referred to as Woodward's rules or the Woodward-Fieser rules.

| Calculated wavelength =                              | total |

Ring substitution on the benzene ring affords shifts to longer wavelengths (Table 7.14) and intensification of the spectrum. With electron-withdrawing substituents, practically no change in the maximum position is observed. The spectra of heteroaromatics are related to their isocyclic analogs, but only in the crudest way. As with benzene, the magnitude of substituent shifts can be estimated, but tautomeric possibilities may invalidate the empirical method.

When electronically complementary groups are situated *para* to each other in disubstituted benzenes, there is a more pronounced shift to a longer wavelength than would be expected from the additive effect due to the extension of the chromophore from the electron-donating group through the ring to the electron-withdrawing group. When the *para* groups are not complementary, or when the groups are situated *ortho* or *meta* to each other, disubstituted benzenes show a more or less additive effect of the two substituents on the wavelength maximum. Calculation of the principal band of selected substituted benzenes is illustrated in Table 7.15.

\* POPOP *p*-bis[2-(5-phenyloxazolyl)]benzene.  
† ANS, anilino-8-naphthalene sulfonic acid.  
‡ TNS, 2-*p*-toluidinylnaphthalene-6-sulfonate.

7.4 FLAME ATOMIC EMISSION, FLAME ATOMIC  
ABSORPTION, ELECTROTHERMAL (FURNACE)  
ATOMIC ABSORPTION, ARGON INDUCTION  
COUPLED PLASMA, AND PLASMA ATOMIC  
FLUORESCENCE

The tables of atomic emission and atomic absorption lines are presented in two parts. In Table 7.18 the data are arranged in alphabetic order by name of the element, whereas in Table 7.19 the sensitive lines of the elements are arranged in order of decreasing wavelengths. For additional lines and their relative intensities consult W. F. Meggers, C. H. Corliss, and B. F. Scribner, *Tables of Spectral-Line Intensities, Part I*, National Bureau of Standards Monograph 32, U.S. Government Printing Office, Washington, D.C., 1961.

The detection limits in the table correspond generally to the concentration of an element required to give a net signal equal to three times the standard deviation of the noise (background) in accordance with IUPAC recommendations. Detection limits can be confusing when steady-state techniques such as flame atomic emission or absorption, and plasma atomic emission or fluorescence, which

**TABLE 7.18** Detection Limits in ng/mL

The detection limits in the table correspond generally to the concentration of analyte required to give a net signal equal to three times the standard deviation of the background in accordance with IUPAC recommendations.

TABLE 7.19 Sensitive Lines of the Elements

In this table the sensitive lines of the elements are arranged in order of decreasing wavelengths. A Roman numeral II following an element designation indicates a line classified as being emitted by the singly ionized atom. In the column headed Sensitivity, the most sensitive line of the non-ionized atom is indicated by U1, and other lines by U2, U3, and so on, in order of decreasing sensitivity. For the singly ionized atom the corresponding designations are V1, V2, V3, and so on.

| Wavelength, nm | Element | Sensitivity | Wavelength, nm | Element | Sensitivity |
|----------------|---------|-------------|----------------|---------|-------------|
| 894.35         | Cs      | U2          | 492.45         | Nd      | U1          |

are steady-state techniques, are compared with the electrothermal or furnace technique which uses the entire sample and detects an absolute amount of the analyte element. To compare the several methods on the basis of concentration, the furnace detection limits assume a 20-μL sample.

Data for the several flame methods assume an acetylene–nitrous oxide flame residing on a 5- or 10-cm slot burner. The sample is nebulized into a spray chamber placed immediately ahead of the burner. Detection limits are quite dependent on instrument and operating variables, particularly the detector, the fuel and oxidant gases, the slit width, and the method used for background correction and data smoothing.

7.4.1 Some Common Spectroscopic Relationships

**7.4.1.1 Electromagnetic Radiation.** Electromagnetic radiation travels in straight lines in a uniform medium, has a velocity of 299 792 500 m · s<sup>-1</sup> in a vacuum, and possesses properties of both a wave motion and a particle (photon). *Wavelength* λ is the distance from crest to crest; *frequency* ν is the number of waves passing a fixed point in a unit length of time. Wavelength and frequency are related by the relation

$$c = \lambda \nu$$

where *c* is the velocity of light (in a vacuum). In any material medium the speed of propagation is smaller than this and is given by the product *nc*, where *n* is the refractive index of the medium.

Radiation is absorbed or emitted only in discrete packets called photons and quanta:

$$E = h\nu$$

where *E* is the energy of the quantum and *h* is Planck’s constant.

The relation between energy and mass is given by the *Einstein equation*:

$$\Delta E = \Delta mc^2$$

where Δ*E* is the energy release and Δ*m* is the loss of mass. Strictly, the mass of a particle depends on its velocity, but here the masses are equated to their rest masses (at zero velocity).

The *Wien displacement law* states that the wavelength of maximum emission, λ<sub>*m*</sub>, of a blackbody varies inversely with absolute temperature; the product λ<sub>*m*</sub>*T* remains constant. When λ<sub>*m*</sub> is expressed in micrometers, the law becomes

$$\lambda_m T = 2898$$

In terms of  $\sigma_m$ , the wavenumber of maximum emission:

$$\sigma_m = 3.48T$$

Another useful version is  $h\nu_m = 5kT$ , where  $k$  is the Boltzmann constant.

*Stefan's law* states that the total energy  $J$  radiated by a blackbody per unit time and area (power per unit area) varies as the fourth power of the absolute temperature:

$$J = aT^{-4}$$

where  $a$  is a constant whose value is  $5.67 \times 10^{-8} \text{ W} \cdot \text{m}^{-2} \cdot \text{K}^{-4}$ .

The relationship between the voltage of an X-ray tube (or other energy source), in volts, and the wavelength is given by the *Duane-Hunt equation*:

$$\lambda = \frac{hc}{eV} = \frac{12\,398}{V}$$

where the wavelength is expressed in angstrom units.

**7.4.1.2 Laws of Photometry.** The time rate at which energy is transported in a beam of radiant energy is denoted by the symbol  $P_0$  for the incident beam, and by  $P$  for the quantity remaining unabsorbed after passage through a sample or container. The ratio of radiant power transmitted by the sample to the radiant power incident on the sample is the *transmittance*  $T$ :

$$T = \frac{P}{P_0}$$

The logarithm (base 10) of the reciprocal of the transmittance is the *absorbance*  $A$ :

$$A = -\log T = \log \left( \frac{1}{T} \right)$$

When a beam of monochromatic light, previously rendered plane parallel, enters an absorbing medium at right angles to the plane-parallel surfaces of the medium, the rate of decrease in radiant power with the length of light path (cuvette interior)  $b$ , or with the concentration of absorbing material  $C$  (in grams per liter) will follow the exponential progression, often referred to as *Beer's law*:

$$T = 10^{-abC} \quad \text{or} \quad A = abC$$

where  $a$  is the absorptivity of the component of interest in the solution. When  $C$  is expressed in moles per liter,

$$T = 10^{-\epsilon bC} \quad \text{or} \quad A = \epsilon bC$$

where  $\epsilon$  is the molar absorptivity.

The total fluorescence (or phosphorescence) intensity is proportional to the quanta of light absorbed,  $P_0 - P$ , and to the efficiency  $\phi$ , which is the ratio of quanta absorbed to quanta emitted:

$$F = (P_0 - P)\phi = P_0\phi(1 - e^{-\epsilon bC})$$

When the terms  $\epsilon bC$  is not greater than 0.05 (or 0.01 in phosphorescence),

$$F = k\phi P_0 \epsilon bC$$

where the term  $k$  has been introduced to handle instrumental artifacts and the geometry factor because fluorescence (and phosphorescence) is emitted in all directions but is viewed only through a limited aperture.

The thickness of a transparent film or the path length of infrared absorption cells  $b$ , in centimeters, is given by

$$b = \frac{1}{2n_D} \left( \frac{n}{\bar{\nu}_1 - \bar{\nu}_2} \right)$$

where  $n$  is the number of fringes (peaks or troughs) between two wavenumbers  $\bar{\nu}_1$  and  $\bar{\nu}_2$ , and  $n_D$  is the refractive index of the sample material (unity for the air path of an empty cuvette). If measurements are made in wavelength, as micrometers, the expression is

$$b = \frac{1}{2n_D} \left( \frac{n\lambda_1\lambda_2}{\lambda_2 - \lambda_1} \right)$$

**7.4.1.3 Grating Equation.** The light incident on each groove is diffracted or spread out over a range of angles, and in certain directions reinforcement or constructive interference occurs, as stated in the grating formula:

$$m\lambda = b(\sin i \pm \sin r)$$

where  $b$  is the distance between adjacent grooves,  $i$  is the angle of incidence,  $r$  is the angle of reflection (both angles relative to the grating normal), and  $m$  is the order number. A positive sign applies where incoming and emergent beams are on the same side of the grating normal.

The *blaze wavelength* is that wavelength for which the angle of reflectance from the groove face and the angle of reflection (usually the angle of incidence) from the grating are identical.

The *Bragg equation*

$$m\lambda = 2d \sin \theta$$

states the condition for reinforcement of reflection from a crystal lattice, where  $d$  is the distance between each set of atomic planes and  $\theta$  is the angle of reflection.

**7.4.1.4 Ionization of Metals in a Plasma.** A loss in spectrochemical sensitivity results when a free metal atom is split into a positive ion and an electron:

The degree of ionization,  $\alpha_i$ , is defined as

$$\alpha_i = \frac{[M^+]}{[M^+] + [M]}$$

At equilibrium, when the ionization and recombination rates are balanced, the ionization constant  $K_i$  (in atm) is given by

$$K_i = \frac{[M^+][e^-]}{[M]} = \left( \frac{\alpha_i^2}{1 - \alpha_i^2} \right) p_{\Sigma M}$$

where  $p_{\Sigma M}$  (in atm) is the total atom concentration of metal in all forms in the plasma.

The ionization constant can be calculated from the *Saha equation*:

$$\log K_i = -5040 \frac{E_i}{T} + \frac{5}{2} \log T - 6.49 + \log \frac{g_{M^+} g_{e^-}}{g_M}$$

where  $E_i$  is the ionization potential of the metal in eV (Table 4.2),  $T$  is the absolute temperature of the plasma (in kelvins), and the  $g$  terms are the statistical weights of the ionized atom, the electron, and the neutral atom. For the alkali metals the final term is zero; for the alkaline earth metals, it is 0.6.

To suppress the ionization of a metal, another easily ionized metal (denoted a *deionizer* or *radiation buffer*) is added to the sample. To ensure that ionization is suppressed for the test element, the product  $(K_i)_{MP_M}$  of the deionizer must exceed the similar product for the test element one hundred-fold (for 1 percent residual ionization of the test element).

## 7.5 INFRARED SPECTROSCOPY

**TABLE 7.20** Absorption Frequencies of Single Bonds to Hydrogen

### Abbreviations Used in the Table

|                         |                                |
|-------------------------|--------------------------------|

\* Conjugation with olefinic or acetylenic groups lowers the frequency and raises the intensity. Conjugation with carbonyl groups usually has little effect on the position of absorption.

TABLE 7.21 Absorption Frequencies of Triple Bonds (Continued)

| Group                                                     | Band, cm <sup>-1</sup>                           | Remarks                                                                                          |
|-----------------------------------------------------------|--------------------------------------------------|--------------------------------------------------------------------------------------------------|

### 7.5.1 Intensities of Carbonyl Bands

Acids generally absorb more strongly than esters, and esters more strongly than ketones or aldehydes. Amide absorption is usually similar in intensity to that of ketones but is subject to much greater variations.

### 7.5.2 Position of Carbonyl Absorption

The general trends of structural variation on the position of  $\text{C}=\text{O}$  stretching frequencies may be summarized as follows:

1. The more electronegative the group X in the system  $\text{R}-\text{CO}-\text{X}-$ , the higher is the frequency.
2.  $\alpha, \beta$  Unsaturation causes a lowering of frequency of  $15$  to  $40 \text{ cm}^{-1}$ , except in amides, where little shift is observed and that usually to higher frequency.
3. Further conjugation has relatively little effect.
4. Ring strain in cyclic compounds causes a relatively large shift to higher frequency. This phenomenon provides a remarkably reliable test of ring size, distinguishing clearly between four-, five-, and larger-membered-ring ketones, lactones, and lactams. Six-ring and larger ketones, lactones, and lactams show the normal frequency found for the open-chain compounds.
5. Hydrogen bonding to a carbonyl group causes a shift to lower frequency of  $40$  to  $60 \text{ cm}^{-1}$ . Acids, amides, enolized  $\beta$ -keto carbonyl systems, and *o*-hydroxyphenol and *o*-aminophenyl carbonyl compounds show this effect. All carbonyl compounds tend to give slightly lower values for the carbonyl stretching frequency in the solid state compared with the value for dilute solutions.
6. Where more than one of the structural influences on a particular carbonyl group is operating, the net effect is usually close to additive.

**TABLE 7.24** Absorption Frequencies of Other Double Bonds*Abbreviations Used in the Table*

## 7.7 NUCLEAR MAGNETIC RESONANCE

**TABLE 7.41** Nuclear Properties of the Elements

In the following table the magnetic moment  $\mu$  is in multiples of the nuclear magneton  $\mu_N(eh/4\pi mc)$  with diamagnetic correction. The spin  $I$  is in multiples of  $h/2\pi$ , and the electric quadrupole moment  $Q$  is in multiples of  $10^{-28}$  square meters. Nuclei with spin  $\frac{1}{2}$  have no quadrupole moment. Sensitivity is for equal numbers of nuclei at constant field. NMR frequency at any magnetic field is the entry for column 5 multiplied by the value of the magnetic field in kilogauss. For example, in a magnetic field of 23.490 kG, protons will process at 4.2576  $\times$  23.490 kG = 100.0 MHz. Radionuclides are denoted with an asterisk.

The data were extracted from M. Lederer and V. S. Shirley, *Table of Isotopes*, 7th ed., Wiley-Interscience, New York, 1978; A. H. Wapstra and G. Audi, "The 1983 Atomic Mass Evaluation," *Nucl. Phys. A* **432**:1–54 (1985); V. S. Shirley, ed., *Table of Radioactive Isotopes*, 8th ed., Wiley-Interscience, New York, 1986; and P. Raghavan, "Table of Nuclear Moments," *At. Data Nucl. Data Tables*, **42**:189 (1989).

TABLE 7.49 Carbon-13 Chemical Shifts (*Continued*)Unsaturated cyclic systems (*continued*)

## Saturated alicyclic ring systems

**TABLE 7.50** Estimation of Chemical Shifts of Alkane Carbons  
*Relative to tetramethylsilane.*

Positive terms indicate a downfield shift.

$$\delta_C = -2.6 + 9.1n_\alpha + 9.4n_\beta - 2.5n_\gamma + 0.3n_\delta + 0.1n_\epsilon \quad (\text{plus any correction factors})$$

where  $n_\alpha$  is the number of carbons bonded directly to the  $i$ th carbon atom and  $n_\beta$ ,  $n_\gamma$ ,  $n_\delta$ , and  $n_\epsilon$  are the number of carbon atoms two, three, four, and five bonds removed. The constant is the chemical shift for methane.

| Chain branching* | Correction factor | Chain branching* | Correction factor |
|------------------|-------------------|------------------|-------------------|
| 1°(3°)           | − 1.1             | 4°(1°)           | − 1.5             |
| 1°(4°)           | − 3.4             | 2°(4°)           | − 7.2             |
| 2°(3°)           | − 2.5             | 3°(3°)           | − 9.5             |
| 3°(2°)           | − 3.7             | 4°(2°)           | − 8.4             |

\* 1° signifies a CH<sub>3</sub>— group; 2°, a —CH<sub>2</sub>— group; 3°, a >CH— group; and 4°, a >C< group. 1° (3°) signifies a methyl group bound to a >CH— group, and so on.

**Examples:** For 3-methylpentane, CH<sub>3</sub>—CH<sub>2</sub>—CH(CH<sub>3</sub>)—CH<sub>2</sub>—CH<sub>3</sub>,

$$\delta_{C=2} = -2.6 + 9.1(2) + 9.4(2) - 2.5 - 1(1)[2^\circ(3^\circ)] = 29.4$$

$$\delta_{C=3} = -2.6 + 9.1(3) + 9.4(2) + (2)[3^\circ(2^\circ)] = 36.2$$

**TABLE 7.51** Effect of Substituent Groups on Alkyl Chemical Shifts

These increments are added to the shift value of the appropriate carbon atom as calculated from Table 7.50.

| Substituent group Y*      | $\alpha$ carbon |          | $\beta$ carbon |          | $\gamma$ carbon |
|---------------------------|-----------------|----------|----------------|----------|-----------------|

**TABLE 7.52** Estimation of Chemical Shifts of Carbon Attached to a Double Bond

The olefinic carbon chemical shift is calculated from the equation

$$\delta_C = 123.3 + 10.6n_\alpha + 7.2n_\beta - 7.9n_\alpha - 1.8n_\beta \quad (\text{plus any steric correction terms})$$

where  $n$  is the number of carbon atoms at the particular position, namely,

Substituents on both sides of the double bond are considered separately. Additional vinyl carbons are treated as if they were alkyl carbons. The method is applicable to alicyclic alkenes; in small rings carbons are counted twice, i.e., from both sides of the double bond where applicable. The constant in the equation is the chemical shift for ethylene. The effect of other substituent groups is tabulated below.

| Substituent group              | $\beta$ | $\alpha$ | $\alpha'$ | $\beta'$ |
|--------------------------------|---------|----------|-----------|----------|
| —OR                            | 2       | 29       | —39       | —1       |
| —OH                            | 6       |          |           | —1       |

## 7.8 MASS SPECTROMETRY

### 7.8.1 Correlation of Mass Spectra with Molecular Structure

**7.8.1.1 Molecular Identification.** In the identification of a compound, the most important information is the molecular weight. The mass spectrometer is able to provide this information, often to four decimal places. One assumes that no ions heavier than the molecular ion form when using electron-impact ionization. The chemical ionization spectrum will often show a cluster around the nominal molecular weight.

Several relationships aid in deducing the empirical formula of the parent ion (and also molecular fragments). From the empirical formula hypothetical molecular structures can be proposed, using the entries in the formula indices of Beilstein and *Chemical Abstracts*.

**7.8.1.2 Natural Isotopic Abundances.** The relative abundances of natural isotopes produce peaks one or more mass units larger than the parent ion (Table 7.75a). For a compound  $\text{C}_w\text{H}_x\text{O}_z\text{N}_y$ , a formula allows one to calculate the percent of the heavy isotope contributions from a monoisotopic peak,  $P_M$ , to the  $P_{M+1}$  peak:

$$100 \frac{P_{M+1}}{P_M} = 0.015x + 1.11w + 0.37y + 0.037z$$

Tables of abundance factors have been calculated for all combinations of C, H, N, and O up to mass 500 (J. H. Beynon and A. E. Williams, *Mass and Abundance Tables for Use in Mass Spectrometry*, Elsevier, Amsterdam, 1963).

Compounds that contain chlorine, bromine, sulfur, or silicon are usually apparent from prominent peaks at masses 2, 4, 6, and so on, units larger than the nominal mass of the parent or fragment ion. For example, when one chlorine atom is present, the  $P + 2$  mass peak will be about one-third the intensity of the parent peak. When one bromine atom is present, the  $P + 2$  mass peak will be about the same intensity as the parent peak. The abundance of heavy isotopes is treated in terms of the binomial expansion  $(a + b)^m$ , where  $a$  is the relative abundance of the light isotope,  $b$  is the relative abundance of the heavy isotope, and  $m$  is the number of atoms of the particular element present in the molecule. If two bromine atoms are present, the binomial expansion is

$$(a + b)^2 = a^2 + 2ab + b^2$$

TABLE 7.75 Isotopic Abundances and Masses of Selected Elements

| (a) Abundances of some polyisotopic elements, % |           |                  |           |                  |           |
|-------------------------------------------------|-----------|------------------|-----------|------------------|-----------|
| Element                                         | Abundance | Element          | Abundance | Element          | Abundance |
| <sup>1</sup> H                                  | 99.985    | <sup>16</sup> O  | 99.76     | <sup>33</sup> S  | 0.76      |
| <sup>2</sup> H                                  | 0.015     | <sup>17</sup> O  | 0.037     | <sup>34</sup> S  | 4.22      |
| <sup>12</sup> C                                 | 98.892    | <sup>18</sup> O  | 0.204     | <sup>35</sup> Cl | 75.53     |
| <sup>13</sup> C                                 | 1.108     | <sup>28</sup> Si | 92.18     | <sup>37</sup> Cl | 24.47     |
| <sup>14</sup> N                                 | 99.63     | <sup>29</sup> Si | 4.71      | <sup>79</sup> Br | 50.52     |
| <sup>15</sup> N                                 | 0.37      | <sup>30</sup> Si | 3.12      | <sup>81</sup> Br | 49.48     |

| (b) Selected isotope masses |         |                  |          |
|-----------------------------|---------|------------------|----------|
| Element                     | Mass    | Element          | Mass     |
| <sup>1</sup> H              | 1.0078  | <sup>31</sup> P  | 30.9738  |
| <sup>12</sup> C             | 12.0000 | <sup>32</sup> S  | 31.9721  |
| <sup>14</sup> N             | 14.0031 | <sup>35</sup> Cl | 34.9689  |
| <sup>16</sup> O             | 15.9949 | <sup>56</sup> Fe | 55.9349  |
| <sup>19</sup> F             | 18.9984 | <sup>79</sup> Br | 78.9184  |
| <sup>28</sup> Si            | 27.9769 | <sup>127</sup> I | 126.9047 |

Now substituting the percent abundance of each isotope (<sup>79</sup>Br and <sup>81</sup>Br) into the expansion,

$$(0.505)^2 + 2(0.505)(0.495) + (0.495)^2$$

gives 
$$0.255 + 0.500 + 0.250$$

which are the proportions of  $P:(P + 2):(P + 4)$ , a triplet that is slightly distorted from a 1:2:1 pattern. When two elements with heavy isotopes are present, the binomial expansion  $(a + b)^m(c + d)^n$  is used.

Sulfur-34 enhances the  $P + 2$  peak by 4.2%; silicon-29 enhances the  $P + 1$  peak by 4.7% and the  $P + 2$  peak by 3.1%.

**7.8.1.3 Exact Mass Differences.** If the exact mass of the parent or fragment ions are ascertained with a high-resolution mass spectrometer, this relationship is often useful for combinations of C, H, N, and O (Table 7.75b):

$$\frac{\text{Exact mass difference from nearest integral mass} + 0.0051z - 0.0031y}{0.0078} = \text{number of hydrogens}$$

One substitutes integral numbers (guesses) for  $z$  (oxygen) and  $y$  (nitrogen) until the divisor becomes an integral multiple of the numerator within 0.0002 mass unit.

For example, if the exact mass is 177.0426 for a compound containing only C, H, O, and N (note the odd mass which indicates an odd number of nitrogen atoms), then

$$\frac{0.0426 + 0.0051z - 0.0031y}{0.0078} = 7 \text{ hydrogen atoms}$$

when  $z = 3$  and  $y = 1$ . The empirical formula is  $\text{C}_9\text{H}_7\text{NO}_3$  since

$$\frac{177 - 7(1) - 1(14) - 3(16)}{12} = 9 \text{ carbon atoms}$$

**7.8.1.4 Number of Rings and Double Bonds.** The total number of rings and double bonds can be determined from the empirical formula ( $\text{C}_w\text{H}_x\text{O}_z\text{N}_y$ ) by the relationship

$$\frac{1}{2(2w - x + y + z)}$$

when covalent bonds comprise the molecular structure. Remember the total number for a benzene ring is four (one ring and three double bonds); a triple bond has two.

### 7.8.1.5 General Rules

1. If the nominal molecular weight of a compound containing only C, H, O, and N is even, so is the number of hydrogen atoms it contains.
2. If the nominal molecular weight is divisible by four, the number of hydrogen atoms is also divisible by four.
3. When the nominal molecular weight of a compound containing only C, H, O, and N is odd, the number of nitrogen atoms must be odd.

**7.8.1.6 Metastable Peaks.** If the mass spectrometer has a field-free region between the exit of the ion source and the entrance to the mass analyzer, metastable peaks  $m^*$  may appear as a weak, diffuse (often humped-shape) peak, usually at a nonintegral mass. The one-step decomposition process takes the general form:

The relationship between the original ion and daughter ion is given by

$$m^* = \frac{(\text{mass of daughter ion})^2}{\text{mass of original ion}}$$

For example, a metastable peak appeared at 147.9 mass units in a mass spectrum with prominent peaks at 65, 91, 92, 107, 108, 155, 172, and 200 mass units. Try all possible combinations in the above expression. The fit is given by

$$147.9 = \frac{(172)^2}{200}$$

which provides this information:

The probable neutral fragment lost is either  $\text{CH}_2=\text{CH}_2$  or CO.

### 7.8.2 Mass Spectra and Structure
